A useful tool for constructing graphs: https://csacademy.com/app/graph_editor/

connected, meaning there is a path between any pair of cities. There are no self-loops (no road connects a city to itself) and no multiple edges between the same pair of cities. Your task is to perform a Breadth-First Search (BFS) starting from node 1 and print the order in which the nodes are visited.

Pseudocode of BFS

The breadth-first-search procedure below assumes that the input graph G = (V, E) is represented using adjacency lists.

BFS(G,s): for each vertex u in G.V: u.colour = 0 $Q = \emptyset$; s.colour = 1ENQUEUE(Q,s) while Q ≠ Ø; u = DEQUEUE(Q)for each v in G.Adj[u]: if v.colour == 0: v.colour = 1ENQUEUE(Q, v) Input

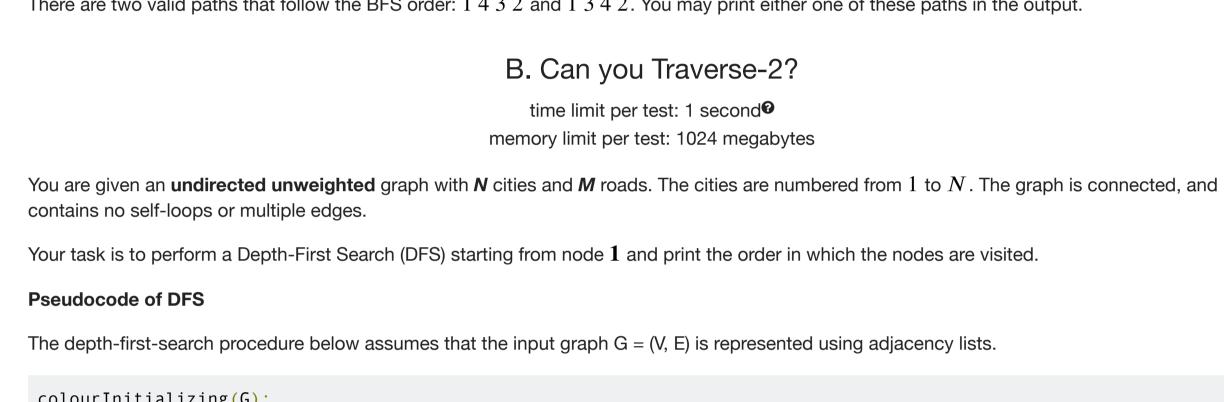

The next M lines will contain two integers $u_i, v_i (1 \le u_i, v_i \le N)$ — denoting there is an edge between city u_i and city v_i . Output Print the BFS traversal starting from node 1 as a space-separated list of visited nodes. If there are multiple BFS path traversal order, you may print **Examples**

The first line contains two integers N and M ($1 \le N \le 2 \times 10^5$, $1 \le M \le 3 \times 10^5$) — the number of cities and the total number of roads.

B. Can you Traverse-2?

time limit per test: 1 second?

memory limit per test: 1024 megabytes

Python has a default recursion limit (usually around 1000) to prevent stack overflow from runaway recursion. As a result, if you are using recursion to solve a problem, you must increase the recursion limit manually. How to Increase the Recursion Depth—

import sys sys.setrecursionlimit(#set_the_value) • What Value to Set— Setting the recursion depth too high can cause a stack overflow or crash your program. This happens because each recursive call uses stack memory, and the system allocates only a limited amount of memory for the stack. If the recursion goes deeper than the system can handle, it may lead to a segmentation fault. Check what the maximum recursion depth might be in your problem. In this problem, the maximum number of nodes the input graph can have is 2×10^5 , so we set the limit accordingly. We add a small buffer (+5, or sometimes +10, +50, etc.) to avoid edge-case runtime errors. import sys sys.setrecursionlimit(2*100000+5) • Choose Python over PyPy to Avoid MLE/RTE — While PyPy is generally faster due to Just-In-Time (JIT) compilation, it also uses more memory.

In recursion-heavy problems, PyPy may consume significantly more stack memory per call compared to CPython. This can lead to Memory Limit

Exceeded (MLE) errors on some platforms, especially when recursion depth is high. Therefore, for problems that involve deep recursion and strict

The first line contains two integers N and M ($1 \le N \le 2 \times 10^5$, $1 \le M \le 3 \times 10^5$) — the number of cities and the total number of roads.

The second line contains M integers $u_1, u_2, u_3 \dots u_m$ $(1 \le u_i \le N)$ — where the i-th integer represents the node that is one endpoint of the i-th

The third line contains M integers $v_1, v_2, v_3 \dots v_m$ $(1 \le v_i \le N)$ — where the i-th integer represents the node that is other endpoint of the i-th

Print the DFS traversal starting from node 1 as a space-separated list of visited nodes. If there are multiple DFS path traversal order, you may print

memory constraints, it is safer to submit your solution using Python (CPython) rather than PyPy.

The i-th edge of this graph is between the i-th node in the second line and the i-th node in the third line.

Сору output D. Through the Jungle time limit per test: 1 second? memory limit per test: 256 megabytes You are given a directed unweighted graph with N nodes and M edges. The nodes are numbered from 1 to N. The graph contains no self-loops or multiple edges. You have to find a shortest path from node S to node D that passes through node K. If multiple such paths exist, print any one of them. If no such path exists, print -1. Input The first line contains five integers N, M, S, D, K $(1 \le N \le 2 \times 10^5, 1 \le M \le 3 \times 10^5, 1 \le S, D, K \le N)$ — the number of vertices, total number of edges, source, destination and the mandatory node that must be included in the path. The next M lines will contain two integers $u_i, v_i (1 \le u_i, v_i \le N)$ — denoting there is an edge from city u_i to city v_i . Output • If a valid path exists from S to D through K, print the length of the path (number of edges) on the first line. • On the second line, print the nodes in the path in order from S to D. • If no such path exists, print -1. **Examples** Сору input 5 10 5 3 5 2 5 5 1 4 5 3 5 1 2 2 4 3 2 1 4 1 3 3 4 Сору output 5 1 3 Сору input 5 4 2 5 3 5 1

time limit per test: 1 second@ memory limit per test: 1024 megabytes There is a tree with **N** nodes. The tree is rooted at a given node **R**. You will be given **Q** queries. In each query, you are asked to find the size of the subtree of a given node **X**. The first line contains two integers N, R ($1 \le N \le 2 \times 10^5$, $1 \le R \le N$) — the number of nodes and the root of the tree. The next N-1 lines each contain two integers $u_i, v_i (1 \le u_i, v_i \le N)$ — representing an bidirectional edge between nodes u_i and v_i . The next line contains an integer $Q(1 \le Q \le 2 \times 10^5)$ — the number of queries. The next Q lines each contain a single integer $X(1 \le X \le N)$ — the node whose subtree size you need to compute. Output For each query, print a single integer — the size of the subtree of node X. **Examples** Сору input Сору output Сору input Сору output Сору input

G. Diamonds under W

time limit per test: 1 second

memory limit per test: 256 megabytes

You may start from any non-obstacle cell and move in the four directions: up, down, left, or right. Your goal is to choose a starting cell such that you

The first line contains two integers R and H ($1 \le R, H \le 1000$) — the number of rows and columns of the grid. The next R lines each contain H

F. Cycle Detection

time limit per test: 1 second?

memory limit per test: 256 megabytes

You are given a directed unweighted graph with N nodes and M edges. The nodes are numbered from 1 to N. The graph contains no self-loops

Write a code to find if there is any cycle in the graph. In graph theory, a cycle in a graph is a non-empty trail in which only the first and last vertices are

The first line contains four integers N and M ($1 \le N \le 2 \times 10^5$, $1 \le M \le 2 \times 10^5$) — the number of vertices and total number of edges.

The next M lines will contain two integers $u_i, v_i (1 \le u_i, v_i \le N)$ — denoting there is an edge from city u_i to city v_i .

Print a single integer — the maximum number of diamonds you can collect starting from a valid cell. **Examples** input 5 5 .#.DD ##.#.

2. D- Cell with a diamond: You can move into this cell and collect the diamond.

output input 5 5

You are given a 2D grid with R rows and H columns.

Each cell in the grid is one of the following:

1. . — Empty cell: You can move into this cell.

3. # — Obstacle: You cannot move into this cell.

can collect the maximum number of diamonds

characters, describing the grid.
